Abstract

Aromatic amines and their derivatives are widely used in the production of dyes, cosmetics, medicines and polymers. However, they pose a threat to the environment due to their hazardous wastes as well as their carcinogenic properties. The objective of the study was to use an alternate strategy i.e. biofield energy treatment and analyse its impact on physicochemical properties of aromatic amine derivatives viz. p-phenylenediamine (PPD) and p-toluidine.

Keywords: Biofield energy treatment; p-Phenylenediamine; p-Toluidine; X-ray diffraction; Surface area analysis; Thermogravimetric analysis; Fourier transform infrared spectroscopy; Ultraviolet-visible spectroscopy

Introduction

Aromatic amines are widely present in natural products, sulphur drugs, dyes, vitamins, amino acids, and nucleic acids [1]. Amines and its salts are known to possess bactericidal, fungicidal and algicidal activities [2]. They are also used in manufacturing of dyes, cosmetics, medicines and rubber. Aromatic secondary amines are used as antioxidants in rubber industries [3]. Aromatic amines have growing interest in the environmental chemistry as they form hazardous waste and also considered as potential carcinogens [4]. p-Phenylenediamine (PPD) is a derivative of the aromatic amine, which is widely used in the organic and coordination chemistry. In the presence of air, it oxidizes to purple and black colour hence, it is mainly used as an ingredient of oxidative hair colouring products [5]. The mechanism is based on the alkaline peroxide oxidation where this diamine is oxidized in combination with other amino and phenolic compounds (modifiers) and gives various shades on hair [6]. Moreover, it is also used as a precursor to certain polymers, plastics and fibres, photographic developing agent and as a histological stain for some lipids [7,8]. p-Toluidine is another aromatic amine that is used in the manufacturing of various dyes, pesticides and pharmaceuticals. It is mainly demanded worldwide for the production of intermediates in pigment synthesis, for example, 4-toluidine-3-sulfonic acid (4B acid), m-nitro-p-toluidine, etc. It is also used as a reagent for lignin, nitrite and chloroglucinol [9,10]. Although these compounds have wide applications but they also create certain toxicity problems. PPD is reported to cause immunologic skin reactions and it is a very common allergen in human [11,12]. Similarly p-toluidine is reported as carcinogenic and may cause cyanosis by oxidation of iron in the haemoglobin ring and converting it to methemoglobin [13,14]. All these problems are associated with the structural properties of aromatic amine derivatives. Hence, some alternative strategies are needed that can alter the physical, thermal and structural properties of these compounds in a cost effective manner. Recently, studies reported that biofield treatment has been known to alter various properties of living organisms and non-living things. A biofield is generated in the form of electromagnetic field due to the motion of charged particles...
such as protons, electrons, and ions in the human body [15]. The energy associated with this field is known as biofield energy and is responsible for communicating information to and among the body. The health of living organisms can be influenced by balancing this energy from the environment through natural exchange process [16]. Biofield therapies are described by National Institute of Health (NIH) and National Centre for Complementary and Alternative Medicine (NCCAM). NCCAM includes biofield therapy as a subcategory of energy medicine among complementary and alternative medicines [17,18]. Almost 43% of the US populations and approximately one-third of the UK populations have been using either form of the healing therapies or the complementary and alternative medicine (CAM) therapy [19]. Thus, the human has the ability to harness the energy from the environment or universe and can transmit it to any living or nonliving object(s) around the Globe. The objects always receive the energy and responding to the useful way. This process is known as biofield energy treatment. Mr. Trivedi’s unique biofield energy (The Trivedi effect®) has been known for its significant impact in the field of material science research [20-22], agriculture research [23,24], microbiology research [25-27] and biotechnology research [28,29]. Hence, based on wide applications of biofield treatment, the current study was designed to evaluate the impact of biofield treatment on physical, thermal and spectroscopic properties of PPD and p-toluidine.

Materials and Methods

p-Phenylenediamine (PPD) and p-toluidine were procured from Loba Chemie Pvt. Ltd., India. Both samples were divided into two parts; one part was kept as a control while the other part was subjected to Mr. Trivedi’s biofield treatment and coded as treated sample. The treated samples in sealed pack were handed over to Mr. Trivedi for biofield treatment under standard laboratory conditions. Mr. Trivedi provided the treatment through his energy transmission process to the treated groups without touching the samples. The biofield treated samples were returned in the same sealed condition for further characterization using XRD, surface area analyser, TGA, FT-IR and UV-Vis spectroscopic techniques.

X-ray diffraction (XRD) study

XRD analysis was carried out on Phillips, Holland PW 1710 X-ray diffractometer system. The X-ray generator was equipped with a copper anode with nickel filter operating at 35 kV and 20 mA. The wavelength of radiation used by the XRD system was 1.54056 Å. The XRD data were acquired over the 2θ range of 10°-99.99° at 0.02° interval with a measurement time of 0.5 seconds per 2θ intervals. The data obtained were in the form of a chart of 2θ vs. relative intensity (%).

\[ \text{Relative Intensity} = \frac{\text{peak intensity counts}}{\text{d value (Å)}} \]

The average size of crystallite (G) was calculated from the Scherrer equation with the method based on the width of the diffraction patterns obtained in the X-ray reflected the crystalline region.

\[ G = \frac{k\lambda}{b\cos\theta} \]

Where, k is the equipment constant (0.94), λ is the X-ray wavelength (0.154 nm), B in radians is the full-width at half of the peaks and θ the corresponding Bragg angle.

Percent change in crystallite size was calculated using the following equation:

\[ \text{Percent change in crystallite size} = \left( \frac{G_{t} - G_{c}}{G_{c}} \right) \times 100 \]

Where, \( G_{c} \) and \( G_{t} \) are crystallite size of control and treated powder samples respectively.

Surface area analysis

The surface area of PPD and p-toluidine were measured by the surface area analyser, Smart SORB 90 based on Brunauer–Emmett–Teller (BET). Percent changes in surface area were calculated using following equation:

\[ \% \text{ change in surface area} = \left( \frac{S_{t} - S_{c}}{S_{c}} \right) \times 100 \]

Where, \( S_{c} \) and \( S_{t} \) are the surface area of control and treated samples respectively.

Thermogravimetric analysis/Derivative thermogravimetry (TGA/DTG)

Thermal stability of control and treated samples of PPD and p-toluidine was analysed using Mettler Toledo simultaneous thermogravimetric analyser (TGA/DTG). The samples were heated from room temperature to 400°C with a heating rate of 5°C/min under air atmosphere. From TGA curve, onset temperature \( T_{onset} \) (temperature at which sample start losing weight) and from DTG curve, \( T_{max} \) (temperature at which sample lost its maximum weight) were recorded.

Spectroscopic studies

For determination of FT-IR and UV-Vis spectroscopic characters, the treated samples were divided into two groups i.e. T1 and T2. Both treated groups were analysed for their spectral characteristics using FT-IR and UV-Vis spectroscopy as compared to respective control samples.

Fourier transform-infrared (FT-IR) spectroscopic characterization

The samples were crushed into fine powder for analysis. The powdered sample was mixed in spectroscopic grade KBr in an agate mortar and pressed into pellets with a hydraulic press. FT-IR spectra were recorded on Shimadzu’s Fourier transform infrared spectrometer (Japan). FT-IR spectra are generated by the absorption of electromagnetic radiation in the frequency range 4000-400 cm\(^{-1}\). The FT-IR spectroscopic analysis of PPD and p-toluidine was carried out to evaluate the impact of biofield treatment at atomic and molecular level like bond strength, stability, rigidity of structure, etc. [30].

UV-Vis spectroscopic analysis

The UV-Vis spectral analysis was measured using Shimadzu UV-2400 PC series spectrophotometer over a wavelength range of 200-400 nm with 1 cm quartz cell and a slit width of 2.0 nm. This analysis was performed to evaluate the effect of biofield treatment on the optical properties of PPD and p-toluidine samples. With UV-Vis spectroscopy, it is possible to investigate the electronic transition between orbitals or bands of atoms, ions and molecules existing in the gaseous, liquid and solid phase [31].

Results and Discussion

X-ray diffraction

X-ray diffraction study was conducted to study the crystalline pattern of the control and treated samples of PPD and p-toluidine (Figure 1). Figures 2 and 3 showed the XRD diffractogram of control...
and treated samples of PPD and p-toluidine, respectively. The XRD diffractograms showed a series of sharp peaks in the regions of 10°<2θ>35°, which depicted that both samples had high crystallinity and long range ordering. From the diffractograms, it was evident that there was no broadening of peaks due to amorphous components, and both samples were found to be crystalline in nature.

The average crystallite size was calculated using Scherrer equation. The crystallite size of PPD samples was found as 96.00 and 106.67 nm in control and treated PPD, respectively. It showed that crystallite size was increased by 11.12% in treated PPD as compared to control (Figure 4). It was previously reported that amino groups present in PPD structure have the tendency to interact via N-H⋯N hydrogen bonds into a polymeric chain. These N-H⋯N interactions generate a three-dimensional network of PPD molecules [32]. It is hypothesized that the treated PPD molecules absorbed the energy through biofield treatment that probably strengthen the hydrogen bonding between amino groups of PPD. These intermolecular interactions might lead to the formation of a polymeric chain-like structure that could lead to increasing crystallite size of treated PPD sample as compared to control.

Besides, the crystallite size of p-toluidine samples was found as 81.21 and 77.31 nm in control and treated sample, respectively. It suggested that crystallite size was decreased by 4.8% in treated p-toluidine as compared to control (Figure 4). It was previously reported that ultrasonic energy can cause the decrease in crystallite size [33]. Recently, our group reported that biofield treatment has produced lattice strain in ceramic nano oxides [20]. Hence, it is hypothesized that biofield energy treatment might transfer some energy that may create some lattice strain within the molecules geometry. This strain may lead to fracturing of grains into subgrains, which resulted in the decreased crystallite size.

**Surface area analysis**

The surface area of control and treated samples of PPD and p-toluidine was investigated using BET method. In PPD, the control sample showed a surface area of 0.377 m²/g; however, the treated sample showed a surface area of 0.409 m²/g. The increase in surface area was 8.49% in the treated PPD sample as compared to control (Figure 4). As it was evident from XRD studies that after biofield treatment, the PPD molecules may form intermolecular chain-like structure [32], hence it could lead to increase the surface area of treated sample as compared to control.

In the p-toluidine sample, the control sample showed a surface area of 0.249 m²/g; however, treated sample showed surface area of 0.228 m²/g. The decrease in surface area of p-toluidine might be due to the decreased crystallite size.
as compared to control. Furthermore, the reduction in T<sub>max</sub> in treated and second decomposition occurred in the temperature range of 170-186.8°C in two steps, in which first weight loss was observed around 120-160°C took place in a single step, which started around 141°C (onset) and completed at 192.69°C in the second step. It was assumed in XRD studies that PPD molecules may form a polymer chain like structure due to intermolecular bonding after biofield treatment. Hence from TGA data, it is hypothesized that the first stage degradation of treated PPD sample might occur due to loss of oligomer like structures and second step might be related to thermal decomposition of treated PPD sample.

TGA/DTG analysis

The thermal degradation of PPD and <i>p</i>-toluidine was studied using thermogravimetric techniques. The TGA and DTG thermograms of control PPD sample (Figure 5) showed that decomposition of sample took place in a single step, which started around 141°C (onset) and completed at 216°C. However, the decomposition of treated PPD proceeded in two steps, in which first weight loss was observed around 120-160°C and second decomposition occurred in the temperature range of 170-220°C. Besides, DTG thermogram data showed that T<sub>max</sub> was found at 186.8°C in control whereas, in treated sample, it was found at 140.72°C (onset) and terminated at 192.69°C (end set). It is hypothesized that biofield treatment might transfer the energy that probably reduces the pore volume of treated sample. It further leads to decreased surface area of treated sample as compared to control.

In case of <i>p</i>-toluidine, TGA thermogram (Figure 6) showed that control sample started to decompose at 96°C (onset) and stopped at 166°C (end set). However, the treated <i>p</i>-toluidine started losing weight at 92°C (onset) and terminated at 153°C (end set). It indicated that onset temperature of treated <i>p</i>-toluidine decreased as compared to control. Besides, DTG thermogram data showed that T<sub>max</sub> was found at 136.03°C in control and 125.28°C in treated sample. It is hypothesized that the first step degradation of treated PPD sample might occur due to loss of oligomer like structures and second step might be related to thermal decomposition of treated PPD sample.

**FT-IR spectroscopic analysis**

Infrared (IR) spectroscopy is based on the vibrations of the atoms in a molecule. When a molecule absorbs infrared radiation, its chemical bonds vibrate and can stretch, contract or bend. FT-IR spectra of control and treated (T1 and T2) samples of PPD and <i>p</i>-toluidine are shown in Figures 7 and 8, respectively. The comparative values of IR peaks of the control sample with treated (T1 and T2) samples are given in Table 1. The major vibration peaks observed were as follows:

**N-H vibrations:** The structure of PPD contains two NH<sub>2</sub> groups at the para position. The vibration peaks corresponding to N-H stretching were observed at 3410 and 3375 cm<sup>-1</sup> in all three samples i.e. control, T1 and T2. Similarly, the N-H bending peak was observed at 798 cm<sup>-1</sup> in all three samples i.e. control, T1, and T2. However, the vibration peak corresponding to C-N-H bending was appeared at 1633 cm<sup>-1</sup> in control sample whereas, at 1627 and 1629 cm<sup>-1</sup> in T1 and T2 sample, respectively.

In case of <i>p</i>-toluidine, the peaks corresponding to N-H stretching were observed at 3419 and 3340 cm<sup>-1</sup> in the control sample and 3419 and 3338 cm<sup>-1</sup> in treated (T1 and T2) samples. The N-H bending peak was observed at 759 cm<sup>-1</sup> in control and T1 samples and 758 cm<sup>-1</sup> in T2 sample. Moreover, the vibration peak corresponding to C-N-H bending was appeared at 1616 cm<sup>-1</sup> in control sample whereas, in treated samples (T1 and T2) it appeared at 1624 cm<sup>-1</sup>.

**Carbon-hydrogen vibrations:** The aromatic structures showed the presence of C-H stretching vibrations in the region 3000-3000 cm<sup>-1</sup> that were the characteristic region. In PPD samples, the peak of C-H stretching was observed at 3009 cm<sup>-1</sup> in all three samples i.e. control, T1, and T2. Similarly, C-H in plane bending peaks was observed at 1130 and 1066 cm<sup>-1</sup> in all three samples i.e. control, T1, and T2. The vibration peak due to C-H out of plane bending was observed at 2912 and 2862 cm<sup>-1</sup> in all three samples i.e. control, T1 and T2.

In PPD sample, the vibration peak belonging to C-C stretching vibrations were observed at 1516 and 1456 cm<sup>-1</sup> in control and T1 samples whereas, at 1514 and 1444 cm<sup>-1</sup> in T2 sample. However, the peak due to C-C deformation was observed at 515 cm<sup>-1</sup> in all three samples i.e. control, T1 and T2.

In the <i>p</i>-toluidine sample, the vibration peak due to C-C stretching was observed at 1516 cm<sup>-1</sup> in control and T1 sample whereas, at 1521 cm<sup>-1</sup> in T2 sample. The peaks due to C-C deformation were appeared at 505 and 462 cm<sup>-1</sup> in control and T1 sample but T2 sample, the peaks were observed at 515 and 462 cm<sup>-1</sup>.

**C-N vibrations:** In PPD sample, the vibration peak belonging to C-N stretching was observed at 1340 cm<sup>-1</sup> in control and T1 samples whereas, at 1342 cm<sup>-1</sup> in T2 sample. The peak due to C-N-C bending was appeared at 1263 cm<sup>-1</sup> in control and T2 samples and at 1265 cm<sup>-1</sup> in T1 sample.
Figure 5: TGA/DTG thermogram of control and treated samples of p-phenylenediamine.
Figure 6: TGA/DTG thermogram of control and treated samples of p-toluidine.
Figure 7: FT-IR spectra of control and treated (T1 and T2) samples of p-phenylenediamine.
Figure 8: FT-IR spectra of control and treated (T1 and T2) samples of p-toluidine.
In the p-toluidine sample, the peak corresponding to C-N stretching was observed at 1338 cm⁻¹ in control and T1 sample and 1340 cm⁻¹ in T2 sample. Similarly, the peak corresponding to C-N-C bending was appeared at 1269 cm⁻¹ in control and T1 samples and at 1271 cm⁻¹ in T2 sample.

**Ring vibration:** The peak due to disubstituted benzene in PPD was appeared at 831 cm⁻¹ in all three samples i.e. control, T1 and T2. However, in the p-toluidine sample, the peak was observed at 813 cm⁻¹ in control and T1 samples but at 821 cm⁻¹ in T2 sample.

The FT-IR spectra of the control sample of PPD and p-toluidine are well supported by literature [37,38]. The FT-IR spectra of treated PPD samples (T1 and T2) showed similar pattern of IR absorption peaks as control sample except C-C aromatic stretching peak in T2 sample which was shifted to lower frequency (1456→1444 cm⁻¹) as compared to control sample. It is already reported that the peak frequency (ν) in IR spectra for any bond is directly proportional to its bond force constant (k). Also, the bond force constant (k) is inversely related to average bond length (r) [22]. Hence, it is presumed that shifting of peak wavenumber corresponding to aromatic C-C bond could be due to change in corresponding bond length after biofield treatment.

The FT-IR spectra of treated p-toluidine (T1 and T2) samples showed similar peaks like in control sample except the peaks corresponding to C-N-H bending and C-H bending in both treated samples (T1 and T2); and vibration peaks due to C-H stretching, disubstituted ring, C-C aromatic stretching and bending in T2 sample (Table 1). The peaks corresponding to C-N-H bending peak was shifted towards higher frequency in both treated samples (1616 cm⁻¹→1624 cm⁻¹) and C-H bending peak was shifted towards lower frequency (675→659 cm⁻¹ in T1 and 675→653 cm⁻¹ in T2) as compared to control. Similarly, the C-H stretching peak was shifted towards lower frequency (2912→2908), and disubstituted ring (813→821), C-C aromatic stretching (1516→1521 cm⁻¹) and C-C bending (505→515 cm⁻¹) peaks were shifted towards higher frequency in T2 sample. These results suggest that biofield treatment might induce some changes in bond length and bond angle corresponding to these bonds in treated samples as compared to control.

**UV-Vis spectroscopic analysis:** In UV spectra of control PPD sample, the absorption peaks were observed at 205, 242 and 308 nm. The treated samples (T1 and T2) showed similar peaks i.e. at 204, 243 and 308 nm in T1 sample and at 204, 242 and 308 nm in T2 sample. Similarly, the control sample of p-toluidine showed absorption peaks at 204, 234 and 290 nm. The treated samples showed similar peaks i.e. at 204, 235 and 290 nm in T1 sample and 202, 234 and 289 nm in T2 sample.

The UV-Vis spectral data suggested that biofield treatment might not cause any significant change in treated PPD and p-toluidine samples in terms of structure or position of functional groups as well as the energy which is responsible for electron transfer between orbitals or bands of atoms, ions and molecules.

**Conclusion**

The XRD results showed 11.12% increase in crystallite size in the biofield treated PPD, which suggests that biofield treatment may induce the intermolecular interactions in the treated PPD sample. However, the crystallite size of treated p-toluidine sample was decreased by 4.8% as compared to the control sample which may be a result of the fracturing of grains into subgrains caused by lattice strain produced via biofield energy. Thermal analysis data revealed that thermal decomposition of biofield treated PPD sample took place in two steps as compared to single step in the control sample. In treated p-toluidine sample, the onset temperature and Tₜₐₙ was reduced as compared to the control sample. On the basis of reduction in these values, it is hypothesized that thermal decomposition of treated p-toluidine sample increased. The FT-IR analysis revealed that vibration peak corresponding to C-C aromatic stretching in treated PPD sample shifted to lower frequency. Moreover, in treated p-toluidine samples, the frequency of peaks corresponding to C-N-H bending, C-H bending, C-H stretching, disubstituted ring, and C-C aromatic stretching and bending were altered as compared to the control sample. These alterations suggest that biofield treatment might induce some changes at bonding level, which ultimately results in the change in frequencies of corresponding peaks. The overall results suggest that the biofield treatment affected the physical, thermal and spectroscopic properties of PPD and p-toluidine samples. However, further studies are needed to elucidate the impact of these findings on the uses and hazards associated with these compounds.
